Heuristic Review #1

Issue

The Google map image was tinted with the colors of pizza hut's logo colors rather a traditional map image.

Heuristic

Consistency and Standards

Explanation

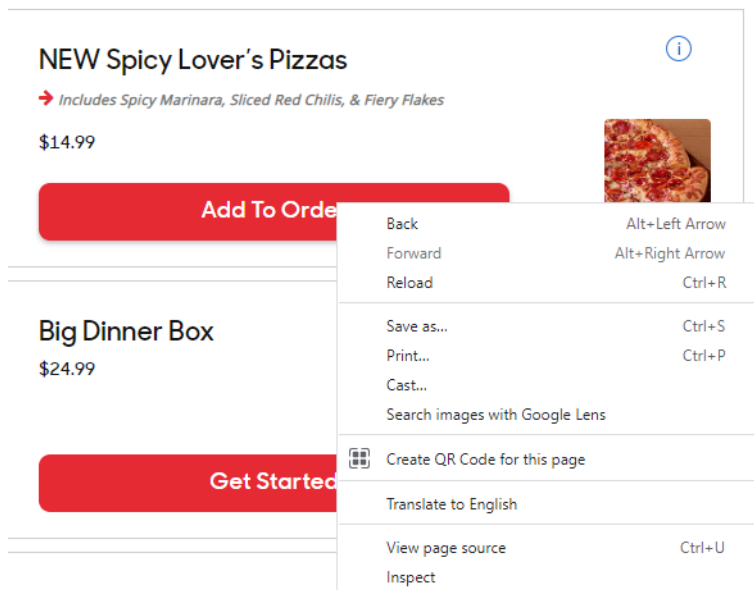

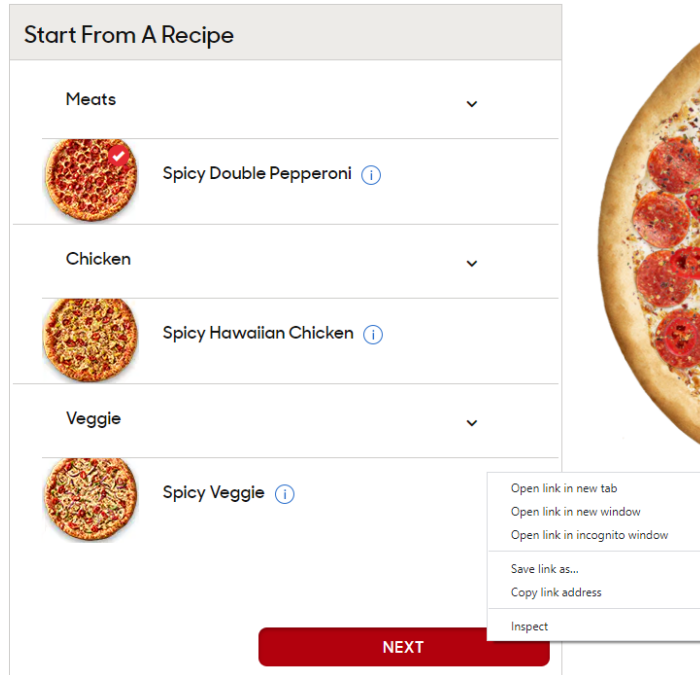

When searching for a restaurant the user can enter a zip code and the app displays a map with locations of restaurants on it. The map itself is tinted red, white, and black, which are the colors of the pizza hut logo and likely a marketing scheme. This violates the heuristic of consistency and standards because almost all other sites display a google map in traditional coloring. This issue is only a severity of 1 because the user can overcome the issue fairly easily. The main purpose of the map is simply to select a restaurant. The restaurants are marked with pins and easy enough to identify which means the user can easily overcome the problem. My problem with this map coloring is that it is difficult to identify roads any smaller than major highways. This means that a user might have a hard time understanding which restaurant is really closest to their desired location. This issue would be especially true for users unfamiliar with the location that they are ordering in.

Heuristic Review #2

Issue

Heuristic

Consistency and Standards / User control and freedom

Explanation

When navigating around pizza hut's website I noticed that some buttons allowed the next page to be opened in a new tab while others did not. I consider this to be a violation of both the consistency and standards and user control and freedom heuristics. As a user I frequently will open pages in new tabs so that if I regress I simply close my current tag. So as a user I found the buttons without the ability to open a new tab frustrating at times. I also believe this is a violation of consistency and standards because the buttons appear exactly the same but function differently for the user. I give this issue a severity score of 1 because of the impact and persistence of the issue. While I found the issue to be annoying it is almost the same experience to click on the button and click on the back button if I regress to the previous page.

Heuristic Review #3

Issue

Unable to use certain characters like “!” in a password.

The screenshot shows a registration form with three input fields: 'Email' containing 'stallkaj@oregonstate.edu', 'Password' with masked characters and a note '(6+ characters, no special characters allowed)', and 'Confirm password' also with masked characters. A white error box on the right side of the form displays the message 'Registration error' followed by 'Your password contains the following invalid character(s): !'. Below the error message is a red button labeled 'TRY AGAIN'.

Heuristic

User control and freedom

Explanation

When trying to create an account and password I was given an error message when trying to use a “!” in my password. Pizza Hut’s website does not allow users to use a “!” in their password which is a violation of the User control and freedom heuristic. I choose to give this issue a score of 2 most because of what the user must do to overcome this issue. The frequency and direct impact are relatively small because a user can simply choose a slightly different password without a “!”. However there are two potential issues I see here, first is that the application is unnecessarily restricting the user, which users who use patterns for passwords might find very annoying. The second is that because the user had to make up a different or alter their password that increases the likelihood that they will forget this password. In my opinion this contributes to the frequency of the issue because it means every time the user logs in they have to remember that they used a slightly different password.

Heuristic Review #4

Issue

Heuristic

Visibility of System Status

Explanation

When loading pages the application would turn the page white and display a moving red bar across the top of the window. This is a violation of the visibility of system status heuristic. This is a violation of the visibility heuristic because it appears to display the status of a page loading but does not show the actual status. This feature is more of a device to just reassure the user that the page is still loading but is meaning itself. I gave this issue a severity score of 1 because it is

simply cosmetic. As a user I would much prefer a system status function that displays the actual status but this issue has practically no impact on the user. Ultimately the user will wait the same amount of time regardless of if they are given a status and this has no impact on using the system beyond that point.
